TITLE: An assembly for welding internal joints of boiler shells. Class 21, No. 187906 [announced by All-Union Scientific Research and Design Engineering Institute of Chemical and Petroleum Apparatus Construction (Vnesoyuznyy nauchno-issledovatel'skiy i proyektnyy institut tekhnologii khimicheskogo i neftyanogo apparatostroyeniya)]

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 21, 1966, 77

TOPIC TAGS: welding, welding equipment, welding technology, seam welding

ABSTRACT: This Author Certificate presents an assembly for welding internal joints of boiler shells. The assembly consists of a column with a frame mounted upon it. The frame carries an arm with a welding head placed on supporting rollers. To maintain a constant position of the electrode in respect to the seam surface, the welding head and arm are connected to one another by a hinge and a spring (see Fig. 1). The latter assures a constant contact between the rollers and the boiler shell. The welding head is hinged to the bearing rollers which are rigidly connected to one another.

"Results of Tests With Brucello-Hydrolysat Used as an Allergic Reagent for Brucellosis Diagnosis," V. M. Krasov, Candidate Biol Sci, All-Union Inst Experimental Vet, 4 pp

"Veter" No 1

Describes results of tests conducted with two brucellosis allergic reagents: 1) abortin, and 2) brucellisate. Former is more effective on cattle, but brucellohydrolysat is most active, specific, and most modern allergic reagent for brucellosis diagnosis. This reagent does not bring about any harmful after-effects in animals.

KRASOV, V. M.

The role of polysaccharides in antigen specificity of higher organisms. V. M. Krasov. *Informatsiya* 25, No. 1, 28(1978); cf. *ibid.* 23, No. 9, 39(1976). Chicken-egg protein yields a polysaccharide which after combination with bacterial protein from *Brucella abortus* equi gives a sharp pptn. reaction with sterile rabbit serum after immunization by the same prepn., and a similar reaction occurs with the egg protein itself. Hence the antigen specificity is associated with the polysaccharide.

Adsorption of the virus of a typical avian plague. V. M. Krasov. *Veterinariya* 26, No. 9, 34(1949).—Adsorption of the virus by $Al(OH)_3$ varies with different specimens of $Al(OH)_3$, in dependence on pH, concn. of Al, stability of the gel, etc. Max. adsorption of 92% is achieved in some cases. Lowering of $Al(OH)_3$ concn. in the gel below 0.2% lowers the adsorption sharply. Dilin. of the virus specimen increases percentage adsorption, but lowers the absolute amt. of adsorbed protein. The process is reversible and the protein is desorbed by shaking with buffer solns. Preliminary communication without detailed data.

Title : Polymolecularity of Specimens of Polyvinyl Chloride Samples
with Different Degree of Conversion.

Orig Pub : Repts. "J. Stefan" Inst, 1956, 3, 203-211

Abstract : Curves are obtained for the distribution of the molecular weight M for polyvinyl chloride with various degrees of polymerization. The samples were rid of impurity and separated by partial precipitation from 0.4% solution of tetrahydrofuran. Water was used as the precipitant. An osmotic and viscosimetric measurement was made of the unseparated samples, and also of the individual fractions. At 20°C, the characteristic viscosity for all specimens with Mn ranging from 20,000 to 120,000 can be represented as $[\eta] = 0.83 \times 10^{-2} M_n^{0.84}$. From the relation between the specific viscosity and the concentration it follows that the polyvinyl chloride molecules in tetrahydrofuran have the forms of rings, which are randomly distributed in magnitude and which are penetrable for the solvent.

Title : Dependence of Molecular Weight on Glass Temperature and Related Properties of Polyvinyl Chloride.

Orig Pub : Repts. "J. Stefan" Inst., 1956, 3, 213-223

Abstract : The authors determine the specific volume, the glass temperature, and the coefficient of thermal expansion of nine fractions of polyvinyl chloride with molecular weight M ranging from 18,600 to 90,000. It is found that the above properties depend on M: the specific volume and the coefficient of thermal expansion increase linearly with increasing 1/M, while the glass temperature diminishes correspondingly. These relations remain the same for homogeneous and for polydispersed specimens, if the data are plotted on a graph as a function of the numerical average of M. On the basis of the measurements, the authors have calculated tentative coefficients of thermal expansion of the middle and end groups of polyvinyl chloride in the solid and liquid states.

7 Characterization of a vinyl chloride/vinyl acetate copolymer. J. P. Krasovec (Inst. "J. Stefan", Ljubljana, Yugoslavia). *Vestnik Sloven. kemi. društva* 4, 97-104 (1957).—A sample of vinyl chloride/vinyl acetate (13%) copolymer was fractionated in 10 fractions ranging from 18,000 to 147,000 mol. wt., and their intrinsic viscosity, mol. wt., and chem. compn. detd. The differential mol. wt. distribution curve showed a narrow distribution with respect to mol. wt. and had a distinct max. at the 35,000 mol. wt. fraction. The chem. compn. of the fractions varied so that their vinyl acetate content decreased the higher the mol. wt. The k' values evaluated by means of the Huggins equation (C.A. 37, 19²) indicate that in tetrahydrofuran soln. the copolymer mols. represent random coils, penetrable by the solvent. The α values decreased with increasing mol. wt. The relation between intrinsic viscosity and mol. wt. in tetrahydrofuran at $20 \pm 0.01^\circ$ is given by the equation: $[\eta] = 9.59 \times 10^{-5} \times M^{0.6}$, applicable only between the 30,000 and 150,000 mol. wt. range. Turbidimetric titration of polymer solutions. P. Kratoch, N. Venc, and A. Peterlin. *J. Polym. Sci. Polym. Chem. Ed.* 15, 165-73 (1957). A method of detg. the mol. wt. distribution in unfractionated samples of poly(vinyl chloride) (I) is described. A precipitant (a 9:1 mixt. of gasoline (b.p. 60-105°) and CCl₄) is added gradually to a dil. soln. of I in cyclohexanone. The turbidity of the soln. is measured as a function of the change in the intensity of scattered light. The scattered light is directly proportional to the amount of pptd. polymer, and its dependence on the vol. of added precipitation is detd. The method is calibrated by titrating solns. of homogeneous fractions of known mol. wt., and plotting their soly. curves. From these the relation between the amt. of precipitant added and the mol. wt. are found, making possible the graphical detn. of distribution curves.

 1 / Dilatometric and nuclear magnetic resonance studies of
 polyethylene with different branching and crystallinity. A.
 Peterlin, B. Kraljic, B. Pirkmajer, and I. Levstek (Univ.
 Ljubljana, Yugoslavia). *Makromol. Chem.* 37, 231-42
 (1960) (in English). — Dilatometric measurements were made
 between room temp. and immediately below the m.p.; they
 showed that the curves of 1st heating differ from those
 of subsequent cooling in all samples except of monocryst.
 prepn. Nuclear magnetic resonance (N.M.R.) was meas-
 ured with low-resolution equipment to det. the derivation
 of absorption curve in 20° intervals from -170° to m.p.
 Samples studied were unbranched Marlex 50 and unbranched
 Du Pont polyethylenes; these gave ratio of the CH₂ end
 groups together with d., n. index, viscosity no. A sharp
 m.p. without relaxation phenomena in pure crystals was
 found by dilatometric investigation while N.M.R. reveals
 that the mobility of polyethylene chains is irreversibly in-
 creased by heating above 73°. Branched samples have re-
 mains of a narrow line; its intensity is proportional to the
 CH₂/CH₃ ratio, even at -170°. N.M.R. spectra are given.

TITLE: Determination of Enthalpy and Specific Heat of Beryllium in the 600 to 2200°K Temperature Range

PERIODICAL: Fizika metallov i metallovedeniye, 1960, Vol.10, No.6, pp.835-837

TEXT: Using twice-distilled beryllium, the present authors measured the enthalpy H of specimens of this metal in the solid state (600 to 1560°K), in the region of the solid-liquid transformation, and in the liquid state (1560 to 2166°K). From the experimental data, the coefficients of the equations for H and specific heat C_p of beryllium, were determined by the method of consecutive approximations. The appropriate equations for the solid state are given by

$$H_T - H_{298.16} = 4.322T + 1.09 \times 10^{-3} T^2 - 1490 \text{ cal/g.at} \quad (1)$$

$$C_p = 4.322 + 2.18 \times 10^{-3} T \text{ cal/°C g.at} \quad (1a)$$

(600 - 1560°K)

Card 1/2

E193/E483

Determination of Enthalpy and Specific Heat of Beryllium in the
600 to 2200°K Temperature Range
and for the liquid state by

$$H_T - H_{298.16} = 6.079T + 2.569 \times 10^{-4} T^2 + 1327 \text{ cal/g at} \quad (2)$$

$$C_p = 6.079 + 5.138 \times 10^{-4} T \text{ cal/°C g at} \quad (2a)$$

(1560 - 2200°K)

The melting point of beryllium was found to be $1557 \pm 5^\circ\text{K}$. the
latent heat of melting being $3520 \pm 80 \text{ cal/g at}$. The results of
the present investigation were in close agreement with those
obtained by L.Losanna (Ref.3). There are 1 figure, 1 table and
7 references: 3 Soviet and 4 non-Soviet.

TITLE: Determination of enthalpy and specific heat of boron oxide
in the range 1000-2200°K

PERIODICAL: Zhurnal fizicheskoy khimii, v. 35, no. 7, 1961, 1499-1501

TEXT: The authors studied a sample prepared by the Vsesoyuznyy nauchno-issledovatel'skiy institut metrologii im. D. I. Mendeleyeva (All-Union Scientific Research Institute of Metrology imeni D. I. Mendeleev). In order to dry the preparation which contained 0.01-0.02% Mg and water, it was slowly heated within 7-8 hr to 600-700°C at a pressure of 10^{-2} mm Hg. It was kept for about 5 hr at this temperature. A formation of bubbles was initially observed which ceased during heating. The sample was then heated up to 1000°C, during one hour, and looked then like colorless transparent glass. Investigation was carried out by means of a massive calorimeter

Determination of enthalpy and specific ...

which consisted of an aluminum block 30 kg with lateral Pt-resistance thermometer. The aluminum block was hermetically enclosed in a vessel which was connected with a vacuum system. Cooling was performed by a double water jacket kept at $25 \pm 0.05^\circ\text{C}$. A vacuum furnace was used for heating, consisting of an electric heater (a graphite tube of 600 mm length and 45 mm diameter), which was surrounded by coaxially arranged cylindrical screens of graphite, tantalum, molybdenum and steel. The temperature was measured by means of a Pt-Rh-Pt thermocouple and an optical 30П-51 (ECP-51) pyrometer. Visual readings were made through a window in the furnace. The error of temperature measurement did not exceed 0.1% up to 1700°K and 0.3% up to 2300°K . The apparatus was evacuated to 10^{-4} mm Hg and then filled with argon (15-20 mm Hg) during the experiment. The ampuls were made from platinum which does not react with B_2O_3 up to 1650°K . Molybdenum was also suitable.

At temperatures above 1600°K the argon pressure was increased to 600-700 mm Hg. The results of measurement are summarized in the Table. The following interpolation formula was used: $H_T - H_{298.16} = 30.54T - 11920 \text{ cal/mole}$ and $C_p = 30.54 \text{ cal/mole-degree}$ ($1000-2150^\circ\text{K}$). There are 1 table and

The effect of the concentration of acids upon their attacking carbon steels. N. A. Baklan and I. I. Krasovitskiy. *J. Applied Chem. U.S.S.R.* 24, 213-17 (1951) (Eng. transl. translation). The relationship between the concn. of acids and the soln. of steels was investigated with 8 different steels with C between 0.05 and 0.9% and Si, Mn, P, S, Cu in varying amts. and can be expressed by the formula $\rho = K a^n$, where K and n are const. When steel is dissolved in H_2SO_4 , K rises from 25.39 to 63.6 with rising % C, in HCl from 1.98 to 4.50, and in CH_3COOH from 0.033 to 0.285. The values of n are 0.07, 0.85, and 0.33, resp., for the 3 acids, a is the activity coeff. of the acid.

TITLE: An experiment to modify wood by polymerization of monomer-impregnated wood under the action of γ radiation

SOURCE: Trudy II Vsesoyuznogo soveshchaniya po radiatsionnoy khimii. Ed. by L. S. Polak. Moscow, Izd-vo AN SSSR, 1962, 511-515

TEXT: The work was undertaken in view of the importance of determining the stability to radiation of certain materials used in nuclear energy technology. Air-dried samples of birch plywood were subjected to γ radiation from a Co⁶⁰ source with an activity of 16,500 g-equiv.Ra at a dosage of 500 r/sec, in a volume of 500 ml, at room temperature. Stability of the wood was affected only at doses in excess of 10^6 r. At 200×10^6 r the wood crumbled between the fingers, owing to destruction of the cellulose macromolecules. Further samples were impregnated with styrene and acrylonitrile, wrapped in cellophane and irradiated. At doses of 5 and 6×10^6 r the

Card 1/2

An experiment to modify

S/844/62/000/000/087/129
D423/D307

stability of samples impregnated with styrene was higher, and those impregnated with acrylonitrile lower than that of the controls. Evidence was obtained that during irradiation not only polymerization of the monomers (filling-in the cavities in the wood structure) but chemical interaction also occurred between the components of the wood and the monomers or polymers. It was shown that styrene actually is partly linked chemically to the wood (i.e. grafted). The percentage of grafted styrene increased with increased dosage. It was also shown that absorption of water by irradiated samples impregnated with styrene was of the same order as the controls, except for samples irradiated at 10×10^6 r. For samples impregnated with acrylonitrile, absorption of water was 30 - 60% less than that of the controls. There are 4 figures and 3 tables.

TITLE: Routes of one-day artificial Earth satellites

SOURCE: Kosmicheskiye issledovaniya, v. 2, no. 4, 1964, 532-538

TOPIC TAGS: one day Earth satellite, artificial Earth satellite,
circular orbit projection, Earth satellite route, route parameter

ABSTRACT: The projections on the surface of the Earth of circular orbits of one-day artificial Earth satellites are analyzed under the assumption that the satellite is influenced only by the Newtonian gravitational field of the Earth. These projections are closed curves for which the following equations are derived:

$$\lambda = \lambda_0 + \arcsin \left(\frac{\lg \varphi}{\lg i} \right) - \arcsin \left(\frac{\sin \varphi}{\sin i} \right),$$

where λ is the geographical longitude, λ_0 is the longitude of the ascending node of the orbit, φ is the geocentric latitude, and i is the inclination of the orbit. With this equation, projection curves are

Card 1/2

L 8786-65

ACCESSION NR: AP4043491

traced for $\lambda_g = 30^\circ \text{ E}, 150^\circ \text{ E}, \text{ and } 90^\circ \text{ W}$ and for λ values in the interval $0^\circ \leq \lambda \leq 180^\circ$. These curves have the form of a lemniscate with its center of symmetry on the equator. For the study of the characteristic features of these curves, the following parameters are introduced: λ_c , the longitude of the center of symmetry; ϕ_{\max} , the maximal value of the latitude attainable on the projection; and $(\Delta\lambda)_{\max}$, the maximal value of the longitudes, equal to $2(\lambda - \lambda_c)$. Working formulas for determining these parameters are derived when λ_k, ϕ_k, A_k (longitude, latitude and azimuth) of the terminal point of the projection of a powered-flight trajectory on the Earth are known. Orig. art. has: 38 formulas and 4 figures.

The product of reduction of 6-nitrodiphenic acid. B. M. Krasovitskiy, D. G. Perevalova, and N. E. Kobayak (Kharkov State Univ.). *Ukrain. Khim. Zhur.* 18, 97-101 (1952) (in Russian); cf. Schmidt and Kämpf, *Ber.* 36, 3738 (1903) - When 6-nitrodiphenic acid is reduced according to S. and K. the resulting product m. 285°, and not higher as reported by them. The material cannot be identified and is not 6-aminodiphenic acid, but phenanthrene-4-carboxylic acid (II). The Ag salt was analyzed and the result corresponds to this structure; HNO₃ regenerates the original acid. I prepd. from HN₃ and fluoranthene-4-carboxylic acid has properties identical with the above. When 6-nitrodiphenic acid is reduced with Na₂S₂O₄, the product, m. 327°, forms a Ag salt having the compn. of I Ag salt; possibly another isomer of I is formed in this instance. G. M. Kosolapoff

3
Azo dyes, derivatives of anilides of diphenic acid. B. M. Kravitskiy and B. S. Khotimskiy (A. M. Gorkii State Univ., Kharkov). *Ukrain. Khim. Zhur.* 18, 1837-1843 (1972) (in Russian).—Azo dyes prepared from substituted anilides of diphenic acid are described; these show good light and weather stability. Comparison of color of these dyes with corresponding ones derived from BzOH indicates that doubling the size of the central unit does not significantly affect the color and other dye properties. Introduction of Br atoms into the 5,5'-positions does not have much effect on the color. Reduction with $\text{Na}_2\text{S}_2\text{O}_4$ of *m*- and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ gave 45-50% of the corresponding *N*-benzoylphenylmethanamines, which were converted to azo dyes by coupling with a series of naphtholsulfonic acids for comparison purposes with the derivs. of the diphenic acid series. Condensation of $\text{o,o}'\text{-(C}_6\text{H}_4\text{COCH}_2\text{)}_2$ with nitroanilines in C_6H_6 , followed by reduction with $\text{Na}_2\text{S}_2\text{O}_4$ gave 40-50% *m*- and *p*-aminoanilides of diphenic acid. These were coupled with 2-naphthol-6-sulfonic acid, 2-naphthol-3,6-disulfonic acid, 2-naphthol-6,8-disulfonic acid, 1,8-dihydroxy-3,6-naphthalenedisulfonic acid, and 1-amino-8-hydroxy-3,6-naphthalenedisulfonic acid, in alk. medium. The resulting dyes did not differ in color or in abs. spectra from the corresponding acids derived from BzOH. Both series of dyes showed very little direct affinity for cotton. All gave yellow-orange to red-violet shades to acid-dyed wool, with abs. max. 480-535 $\text{m}\mu$. The coupling product of diphenic acid *m*-aminoanilide with 2-naphthol-3,6-disulfonic acid had abs. max. 490 $\text{m}\mu$; that with 1,8-dihydroxy-3,6-naphthalenedisulfonic acid had abs. max. 520 $\text{m}\mu$; that with 1-amino-8-hydroxy-3,6-naphthalenedisulfonic acid had abs. max. 530 $\text{m}\mu$. The 2nd dye after chrome treatment changed its color to green. Ice colors formed on cotton with Azotol A ranged from red to brown. Dyes with 3-hydroxyphenanthrene coupling agent were more deeply colored than those with 2-naphthol. The dye from coupling of the *m*-aminoanilide of diphenic acid with 3-hydroxyphenanthrene had abs. max.

(over)

515 mμ; that derived from 2-naphthol had abs. max. 490 mμ. These were insol. in alkalis as expected. Coupling diazotized aminoanilides of diphenic acid or NaOH with 1-naphthol, 2-chloro-1-naphthol, or 4-bromo-1-naphthol gave p-hydroxy azo dyes, the 1st 2 of which were unstable in alkali, while the last case gave a dye insol. in alkali, since the coupling took place in the 2-position of naphthol; the abs. max. of these 3 dyes were, resp., 480 mμ, 505 mμ, and 500 mμ. Condensation of diphenic anhydride with m- or p-nitroanilines in CaH_2 gave 85-90% of the corresponding nitromonoanilides, which with $\text{Na}_2\text{S}_2\text{O}_4$ were reduced to 50-60% of the corresponding m- and p-aminoanilides, isolated as HCl salts. These were dissolved in 10% Na_2CO_3 , treated with NaNO_2 , and the mixts. added to a large excess of concd. HCl; the diazotized substances were coupled with the same components as are listed above. The resulting dyes gave yellow-orange to red-violet colors on wool. Abs. max. of EtOH solns. of the dyes from mono-m-aminoanilide (I) of diphenic acid with 2-naphthol is about 500 mμ, as is that of the corresponding dianilide; with p-amino coupling agent the abs. max. was about 490 mμ. I coupled with 2-naphthol-6,8-disulfonic acid gave a dye with abs. max. 480 mμ; the p-amino deriv., abs. max. 500; I with 2-naphthol-6-sulfonic acid gave a dye with abs. max. 490 mμ; the p-amino analog has abs. max. 495 mμ; I with 1-naphthol-4-sulfonic acid gave a dye with abs. max. 490; p-amino analog 510; I with 2-naphthol-3,6-disulfonic acid gave a dye with abs. max. 490; p-amino analog 510; I with 1,8-dihydroxy-3,6-naphthalenedisulfonic acid gave a dye with abs. max. 520; p-amino analog 530; I with 1-amino-8-hydroxy-3,6-naphthalenedisulfonic acid gave a dye with abs. max. 530; p-amino analog 535 mμ. Chrome treatment dulls the colors of these dyes but makes them somewhat deeper on wool, with an increase of fastness. Bromination of phenanthrenequinone, followed by oxidation gave 3,5-dibromo-diphenic acid, which was converted to the respective bis-(aminoanilide) and mono-m- and p-aminoanilides; the 1st

was diazotized by means of nitrosylsulfuric acid, the last 2 were diazotized as described above by conventional methods. These coupled with the components listed above produced azo dyes that dyed wool from orange to red-violet shades with considerable fastness. Chrome treatment deepened their colors and increased fastness, with some loss in brightness. The colors formed by coupling on cotton with azotols gave red colors. The abs. max. of these dyes lie within 3 mμ of those of the unsubstituted analogs.
